

Daily Vedic Astro

What to do next - step-by-step launch guide

SOURCE READY

BACKEND VERIFIED

NEXT: CREDENTIALS + RELEASE

For the project located at:

C:\Users\mamat\OneDrive\Documents\10rs vedic

Prepared 24 June 2026

Your launch path

The application code is complete and verified. Your next work is mainly account setup, credentials, real provider integration, device testing and store review. Complete the stages in this order so later steps do not have to be repeated.

Important distinction

The app can be previewed immediately with local data and OTP 123456. A public production release must use a real OTP provider, a Lahiri sidereal astrology provider, live store products and production Cloudflare secrets.

Run the app locally

01

Confirm the app opens and the parent-friendly journey feels right.

Create Cloudflare resources

02

Provision D1, apply the schema and deploy the Worker API.

Connect real OTP

03

Deliver secure phone or email verification without preview codes.

Connect Vedic calculations

04

Replace preview values with sidereal, Lahiri-based chart data.

Configure subscriptions

05

Create Apple/Google products and validate premium entitlement.

Initialize EAS

06

Connect the Expo project and create an installable preview APK.

Test notifications

07

Verify daily, weekly and monthly reminders on real devices.

Complete legal/store content

08

Publish support, privacy, terms, screenshots and listing copy.

Run release QA

09

Exercise every access state, device size and destructive account action.

Build and submit

10

Produce Android AAB and iOS builds, then release gradually.

Keep these files open while working

README.md, worker/wrangler.toml, worker/.dev.vars.example, .env.example, worker/PROVIDER_CONTRACT.md and eas.json.

Local run and Cloudflare deployment

Finish this page before purchasing provider plans or submitting store builds.

1

Run the mobile app locally

Outcome: the full preview journey works in Expo Go or web.

Open PowerShell in the project folder and run:

```
cd "C:\Users\mamat\OneDrive\Documents\10rs_vedic"  
npm install  
Copy-Item .env.example .env  
npx expo start
```

- [] Open the QR code with Expo Go, or press W for the web preview.
- [] Sign in with any test phone/email and use preview OTP 123456.
- [] Complete birth details and verify Home, Daily, Panchang, Remedies, Chart and Profile.
- [] Switch between light and dark mode and confirm large text remains readable.

Success signal

You reach the Home screen and see a 30-day trial card. Preview readings show a 'Preview calculation' label.

2

Create the Cloudflare Worker and D1 database

Outcome: a deployed HTTPS API with persistent users and trials.

Create or sign in to a Cloudflare account, then authenticate Wrangler and create the database:

```
npx wrangler login  
cd worker  
npx wrangler d1 create daily-vedic-astro
```

Copy the returned database ID into **worker/wrangler.toml** in place of **replace-with-your-d1-database-id**. Then prepare a strong local secret and test the migration:

```
Copy-Item .dev.vars.example .dev.vars  
npx wrangler d1 migrations apply daily-vedic-astro --local  
npx wrangler dev
```

Secret rule

JWT_SECRET must contain at least 32 random characters. Never put Worker secrets in an EXPO_PUBLIC_ variable or commit .dev.vars.

Authentication and Vedic calculations

These are the two integrations that turn preview mode into a trustworthy service.

3

Connect a real OTP delivery provider

Outcome: production users receive phone or email verification codes.

- [] Choose an SMS/email provider that can reliably serve your target Indian users.
- [] Create a small secure endpoint that accepts identifier, code, purpose and expiry.
- [] Set `OTP_PROVIDER_URL` in `worker/wrangler.toml`.
- [] Store `OTP_PROVIDER_TOKEN` with: `npx wrangler secret put OTP_PROVIDER_TOKEN`
- [] Deploy and verify that production responses never include `devOtp`.

Expected provider request

The Worker sends identifier, a six-digit code, purpose 'Daily Vedic Astro sign-in' and a ten-minute expiry. See `README.md` for the exact JSON body.

4

Connect a Lahiri sidereal astrology provider

Outcome: Rashi, Nakshatra, Lagna and Panchang use real calculations.

- [] Confirm the provider supports sidereal zodiac and Lahiri ayanamsa.
- [] Confirm it accepts date, exact time, timezone, place and coordinates.
- [] Confirm chart responses include Rashi, Nakshatra, Lagna and basic dasha.
- [] Confirm Panchang responses include Tithi, Yoga, Karana, sunrise/sunset and local caution periods.
- [] Review licensing terms for caching and consumer display.
- [] Ask a qualified Vedic astrologer to validate sample calculations before launch.

Implement the exact request/response contract in `worker/PROVIDER_CONTRACT.md`, then configure:

```
cd worker
npx wrangler secret put ASTROLOGY_PROVIDER_KEY
# Set ASTROLOGY_PROVIDER_URL in wrangler.toml
```

Do not skip

Production is intentionally designed to fail safely when the astrology provider is absent. Do not change it to silently serve estimated values.

Store subscriptions

Digital premium access must continue to use Apple and Google billing. RevenueCat is the entitlement and validation layer, not a custom payment gateway.

5

Create and verify the ₹10 monthly plan

Outcome: purchase, restore and renewal state work on both platforms.

A. Create the accounts

- [] Enroll in the Apple Developer Program and create the app in App Store Connect.
- [] Create a Google Play Console developer account and app.
- [] Create a RevenueCat project for Daily Vedic Astro.

B. Create matching products

- [] Use product ID: daily_vedic_astro_monthly_10 on Apple and Google.
- [] Set a monthly auto-renewing subscription and choose the closest allowed ₹10 India price point.
- [] Create RevenueCat entitlement: premium, then attach both products.

C. Configure app and Worker keys

```
# EAS public build variables
EXPO_PUBLIC_REVENUECAT_IOS_KEY=appl...
EXPO_PUBLIC_REVENUECAT_ANDROID_KEY=goog...

# Worker secrets
npx wrangler secret put REVENUECAT_SECRET_KEY
npx wrangler secret put REVENUECAT_WEBHOOK_SECRET
```

D. Configure and test the webhook

- [] Webhook URL: https://YOUR-WORKER/subscription/webhook
- [] Authorization header: Bearer YOUR_REVENUECAT_WEBHOOK_SECRET
- [] Test initial purchase, renewal, cancellation, expiration and restore.
- [] Confirm access changes in GET /subscription/status.

Trial behavior

The service trial starts once on profile creation and lasts 30 days. It is linked to the account identifier. Deleting and recreating an account does not restart the trial.

Never test live money first

Use Apple sandbox/TestFlight and Google Play internal testing accounts before any public rollout.

EAS builds and notifications

Create an installable APK early. Store billing and realistic push behavior require a development or EAS build, not only Expo Go.

6

Initialize EAS and create the preview APK

Outcome: the app installs on a physical Android phone.

```
cd "C:\Users\mamat\OneDrive\Documents\10rs_vedic"
npx eas-cli@latest login
npx eas-cli@latest init
eas build --platform android --profile preview
```

- [] Store the generated EAS project ID as EXPO_PUBLIC_EAS_PROJECT_ID.
- [] Add production EXPO_PUBLIC_API_URL pointing to the deployed Worker.
- [] Install the APK on at least one current and one older Android phone.
- [] Verify launch, login, scrolling, back navigation and subscription messaging.

7

Test push and local reminders

Outcome: reminders arrive at the time selected in Profile.

- [] Use a physical Android and iPhone; simulators are not sufficient for final push testing.
- [] Enable reminders from Profile and accept the system permission prompt.
- [] Verify the daily reminder and tap it to open Daily guidance.
- [] Verify the weekly reminder on Monday and monthly reminder on the first day.
- [] Change the reminder time and verify the old schedules are replaced.
- [] Disable reminders and confirm scheduled notifications are removed.

Current implementation

Daily, weekly and monthly reminders are scheduled locally on the device. The Expo push token is also stored in D1, ready for future server-driven campaigns.

Legal, store content and release QA

Do not submit until the following operator-owned information replaces every placeholder.

8

Complete legal and store information

Outcome: policies and listing content identify the real app operator.

- ☐ Add company or proprietor legal name, postal address and support email.
- ☐ Host Privacy Policy and Terms at public HTTPS URLs.
- ☐ Update app/privacy.tsx and app/terms.tsx with the final operator details.
- ☐ Prepare store title, short description, full description and support URL.
- ☐ Capture light and dark screenshots from real phone-sized builds.
- ☐ Complete Apple privacy nutrition labels and Google Data Safety accurately.
- ☐ Explain birth data, OTP, subscription entitlement and notification usage.
- ☐ Verify Delete Account is easy to find and removes raw profile/birth data.

Content safety

Use guidance language only. Avoid fear, guaranteed outcomes, diagnosis, death, accident, marriage certainty or investment claims.

9

Run the release QA matrix

Outcome: every critical state passes on Android and iOS.

State	Must verify
New user	OTP, onboarding, privacy message and 30-day trial
Trial user	Full daily, weekly, monthly, Panchang, remedies and chart
Expired user	Basic daily message only; premium sections visibly locked
Paid user	Purchase, restore, renewal, cancellation and expiration
Offline	Saved profile opens calmly; no false purchase or calculation success
Account deletion	Raw data removed; trial cannot be reset; store cancellation explained
Accessibility	Large text, screen reader labels, color contrast and 44px controls

Build, submit and monitor

When all prior checkboxes are complete, create release builds from a clean working tree.

10

Create production builds and submit

Outcome: controlled internal testing, then a gradual public release.

```
npm run typecheck
npm run lint
npx expo-doctor

eas build --platform android --profile production
eas build --platform ios --profile production

eas submit --platform android --profile production
eas submit --platform ios --profile production
```

Before pressing Submit

- [] Worker ENVIRONMENT is production and preview data is disabled.
- [] Remote D1 migration is applied and the deployed / endpoint returns status ok.
- [] OTP, astrology and RevenueCat secrets exist only in Worker/EAS secret stores.
- [] Production app uses the deployed HTTPS Worker URL.
- [] Product IDs and entitlement ID match exactly across code, stores and RevenueCat.
- [] Support, terms and privacy URLs are live and accessible without login.
- [] At least one Android internal test and one TestFlight session passed end to end.

Recommended release sequence

1. Google Play internal testing. 2. TestFlight internal testing. 3. Small closed beta with trusted families. 4. Fix feedback. 5. Gradual public rollout. Avoid opening to everyone on the first production build.

Monitor after release

Watch OTP delivery failures, astrology provider errors, subscription webhooks, crash-free sessions, account deletions and user reports. Pause rollout if login, billing or chart generation becomes unreliable.

Your immediate next action

Start with Step 1 today. After local confirmation, create the Cloudflare D1 database in Step 2. Do not purchase every service at once; connect and test one provider at a time.
